

Microsoft Excel is a software program produced by Microsoft that allows users to organize, format and calculate data with formulas using a spreadsheet system. This software is part of the Microsoft Office suite and is compatible with other applications in the Office suite.

Features of ms excel ..

Recommended Charts

Many Excel users don't always know the best chart type for their data. With the **Recommended Charts** feature, Excel displays a collection of suggested chart types for the selected data. You'll see a preview of how your data looks in different charts and then simply pick the one that displays your results that way you want to present. Although Recommended Charts can help inexperienced users create charts that explain the data and don't confuse the audience, it's a handy tool for all Excel users who want a quick, professional chart.

Instant Data Analysis

The new **Quick Analysis** tool helps both new and experienced Excel users find options for showing data in meaningful ways. Just select the data you want to analyze and then click on the Quick Analysis button that appears to the bottom right of your selected data (or press **[Ctrl] + Q**). Preview your data for conditional formatting, Sparklines, tables or charts, and make your choice stick in just one cli

Instant Answers with PivotTables

Excel PivotTables are a powerful tool for analyzing, summarizing, and answering questions about your data but some users find them difficult to create. Thanks to another of the Excel 2013 new features, the **Recommended PivotTables** option, you can quickly create a meaningful PivotTable with just a click. To try these, start inside your data (which must have column headings), and choose **Insert > Recommended PivotTables**.

Pointer Shapes As with other Microsoft programs, the pointer often changes its shape as you work in Excel. Each pointer shape indicates a different mode of operation. This table shows the various pointer shapes you may see while working in Excel

As with other Microsoft programs, the pointer often changes its shape as you work in Excel. Each pointer shape indicates a different mode of operation. This table shows the various pointer shapes you may see while working in Excel.

Shape	Context	Action
	The default pointer shape; appears in most Excel workspace contexts	Moves cell pointer or selects a range of cells
	Appears when the pointer is on the border of a window	Adjusts window size
	Appears when the pointer is between a row or column divider	Adjusts height and width of rows and columns
	Appears when you are editing cell contents	Provides a text insertion point
	Appears when the pointer is on a column or row heading	Selects columns or rows
	Appears when the pointer is placed over a cell border, graphic, or other object	Moves cells, graphics, or objects
	Appears when the pointer is on the "fill corner" of a cell or cell range	AutoFills other cells with similar information
	Appears when mouse is placed over the Ribbon	The standard Microsoft Windows pointer; selects Ribbon and menu options

Cells are the small rectangular boxes that make up the spreadsheet. The boxes are the intersection of columns (A, B, C, etc.) and rows (1, 2, 3, etc.). To reference a cell, use the column the row name. For example, the cell in the first column and first row is called "A1". All the information entered into an Excel spreadsheet is entered into cells.

Formatting Cells

Cells are the small rectangular boxes that make up the spreadsheet. All the information entered into an Excel spreadsheet is entered into cells. The cell width and height will usually need to be adjusted to view all the information entered into a cell. To adjust the cell width, move the mouse pointer in between two cell columns in the column header. Hold down the left mouse button and drag the mouse left to shorten the width or right to expand the width. Notice that all cells within the column are automatically adjusted. Adjust the cell height using the same method. Move the mouse cursor between two rows, hold down the left mouse button and move the mouse up to decrease the height and down to increase the height. Before you begin entering data,

Inserting Rows and Columns

When you are working on a spreadsheet, you may realize that you left out a row or column of data and need to add it in. To insert a row, click on the row below where you want your new row to be (remember to click on the row number to highlight the entire row). From the “Home” tab, within the “Cells” box, click “Insert.” Select “Insert Sheet Rows.” A new row will automatically be inserted and the row numbers automatically adjusted. To insert a column, click on the column to the right of where you want your new column to be (remember to click on the column letter to highlight the entire column). From the “Home” tab, within the “Cells” box, click “Insert.” Select “Insert Sheet Columns.” A new column will automatically be inserted and the column letters automatically adjusted.

Basic Formulas

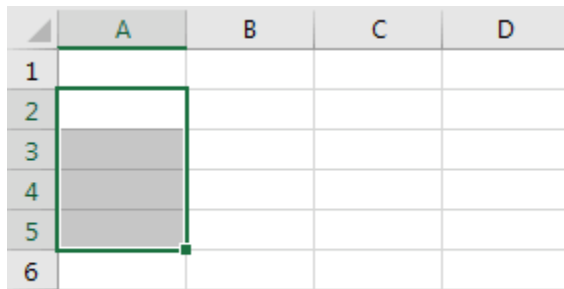

Excel can calculate basic equations like addition, subtraction, multiplication, and division. Let’s say you just want to add two numbers, with the answer appearing in a particular cell. (As you may remember, all formulas begin with an = sign. This lets Excel know that you are entering a formula.) To write a formula that adds two numbers together (for example, 181 + 376): 1. Click on the cell where you want the answer to the equation to appear. 2. Begin by typing the = sign. 3. Type the numbers you want to add separated by the + sign (without spaces): 181+376. 4. Your entire equation should look like this: =181+376 5. Press the Enter key. 6. You will now see the sum appear in the cell – in this case, 557.

AutoSum and Excel Equations One of the most powerful features of Excel is its ability to perform basic math functions on data. Excel can add, subtract, multiply, divide, find the average, and perform general counting functions on the numerical data that you enter. To enable this feature, highlight all of the cells in a column, plus one additional empty cell in which to display the result. Select the AutoSum icon from the ribbon menu: If you click directly on the Σ , Excel will automatically add up the numbers you have selected. If you click on the little dropdown arrow next to it .

A **CELL range** is a group or block of cells in a [worksheet](#) that are selected or highlighted.

Vertical Range

This vertical range is A2:A5. In this example, if you had selected the entire column A, the range would be A:A.

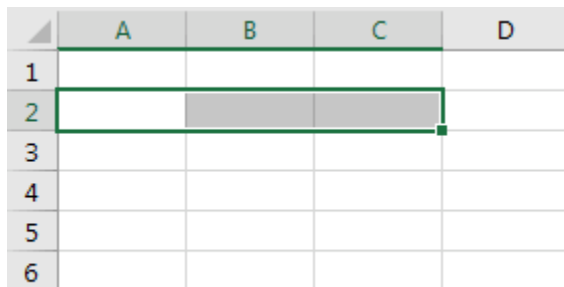

An Excel spreadsheet with columns A, B, C, and D, and rows 1 through 6. The cells in column A, rows 2 through 5 (A2:A5), are highlighted with a green border and a gray fill, indicating a vertical range selection. A small green square is visible at the bottom-right corner of the selection (cell A5).

Horizontal Range

This horizontal range is A2:C2. In this example, if you selected the entire row 2, the range would have be 2:2.

An Excel spreadsheet with columns A, B, C, and D, and rows 1 through 6. The cells in row 2, columns A through C (A2:C2), are highlighted with a green border and a gray fill, indicating a horizontal range selection. A small green square is visible at the bottom-right corner of the selection (cell C2).

MS excel Chart :

In general, a **chart** is a graphical representation of data. Charts allow users to see what the results of data to better understand and predict current and future data.

Types of charts

There are a wide variety of charts available to display data. The list below contains those that are most popular and supported by many programs.

Bar chart

Updated: 10/02/2017 by Computer Hope

Alternatively referred to as a **bar graph**, a **bar chart** is a [graphic](#) representation of [data](#). Bar charts show [horizontal](#) or [vertical](#) bars going across the chart horizontally, with the values displayed on the bottom of the chart.

Bar Chart Overview

Column chart

Updated: 04/01/2018 by Computer Hope

A **column chart** is a [graphic](#) representation of [data](#). Column charts display [vertical](#) bars going across the chart horizontally, with the values [axis](#) being displayed on the left side of the chart.

Line chart

Updated: 10/11/2017 by Computer Hope

Alternatively referred to as a **line graph**, a **line chart** is a [graphic](#) representation of [data](#) that is plotted using a series of lines. Line charts display lines going across the chart [horizontally](#), with the values [axis](#) being displayed on the left side of the chart.

A **pie chart** is a circular [chart](#) that is sliced into sections (similar to slicing a pie you would eat), each section represents a percentage.

Functions in MS excel :

Function Description

The Excel PMT function calculates the constant periodic payment required to pay off (or partially pay off) a loan or investment, with a constant interest rate, over a specified period.

The syntax of the function is:

PMT([rate](#), [nper](#), [pv](#), [\[fv\]](#), [\[type\]](#))

rate	- The interest rate, per period.
nper	- The number of periods over which the loan or investment is to be paid.
pv	- The present value of the loan/investment.
[fv]	- An optional argument that specifies the future value of the loan/investment, at the end of nper payments. If omitted, [fv] has the default value of 0.
[type]	- An optional argument that defines whether the payment is made at the start or the end of the period. This can have the value 0 or 1, meaning: 0 - the payment is made at the end of the period; 1 - the payment is made at the beginning of the period.

unction Description

The Excel PPMT function calculates the payment on the principal, during a specific period of a loan or investment that is paid in constant periodic payments, with a constant interest rate.

The syntax of the function is:

PPMT(*rate*, *per*, *nper*, *pv*, [*fv*], [*type*])

Where the arguments are as follows:

<i>rate</i>	-	The interest rate, per period.
<i>per</i>	-	The period for which the payment on the principal is to be calculated (must be an integer between 1 and <i>nper</i>).
<i>nper</i>	-	The number of periods over which the loan or investment is to be paid.
<i>pv</i>	-	The present value of the loan/investment.
[<i>fv</i>]	-	An optional argument that specifies the future value of the loan/investment, at the end of <i>nper</i> payments. If omitted, [<i>fv</i>] takes on the default value of 0.
[<i>type</i>]	-	An optional argument that specifies whether the payment is made at the start or the end of the period. This can have the value 0 or 1, meaning: 0 - The payment is made at the end of the period; 1 - The payment is made at the start of the period. If the [<i>type</i>] argument is omitted, it takes on the default value of 0 (denoting payments made at the end of the period).

The Excel IPMT function calculates the interest payment, during a specific period of a loan or investment that is paid in constant periodic payments, with a constant interest rate.

The syntax of the function is:

IPMT(*rate*, *per*, *nper*, *pv*, [*fv*], [*type*])

Where the arguments are as follows:

<code>rate</code>	- The interest rate, per period.
<code>per</code>	- The period for which the interest payment is to be calculated (must be an integer between 1 and <code>nper</code>).
<code>nper</code>	- The number of periods over which the loan or investment is to be paid.
<code>pv</code>	- The present value of the loan/investment.
<code>[fv]</code>	- An optional argument that specifies the future value of the loan/investment, at the end of <code>nper</code> payments. If omitted, <code>[fv]</code> takes on the default value of 0.
<code>[type]</code>	- An optional argument that defines whether the payment is made at the start or the end of the period. This can have the value 0 or 1, meaning: <ul style="list-style-type: none"> 0 - The payment is made at the end of the period; 1 - The payment is made at the start of the period.

Mathematical function:
